ADA & Universal Principles

This diagram applies universal principles of accessible design through a continuous, legible path of travel that connects parking, entry, and interior program without interruption. The primary circulation spine operates as an unbroken accessible route, integrating ramps, corridors, and vertical circulation into a cohesive system rather than a series of isolated accommodations.

Slope and topography are treated as extensions of movement, with ramps embedded into the ground plane to maintain a consistent and gradual transition across level changes. These elements follow a uniform gradient, allowing accessibility to be experienced as fluid continuity rather than discrete intervention. Landings are positioned at key intervals, doubling as moments of pause and spatial orientation within the circulation sequence.

Turning radii are strategically placed at nodes of intersection, including restrooms, elevator lobbies, and points of directional change. These circular clearances ensure full maneuverability while reinforcing spatial clarity, allowing users to navigate intuitively through the plan. Rather than leftover space, these zones act as calibrated moments of negotiation between paths.

Width is treated as a performative dimension, maintaining consistent clearances along primary routes while expanding at points of convergence to accommodate increased flow and accessibility needs. This modulation of space allows circulation to operate efficiently under both everyday use and peak occupancy conditions.
