

A3

Program Spatial Strategy

The spatial strategy organizes program as a dense, interlocking cluster within the faceted envelope rather than as conventional stacked floor plates. The diagrid structural skin defines the outer geometry while interior volumes shift, overlap, and cantilever to create spatial diversity within a compact mass. Section is the primary design instrument, vertical voids and offset floor plates allow visitors to perceive multiple program layers simultaneously, reinforcing the building's identity as a single interconnected organism rather than a stack of isolated rooms. The building's form tapers and extends at the base, pulling the ground plane into the structure and dissolving the conventional threshold between site and interior. This extended base creates a continuous landscape approach from the waterfront and surrounding streets, while the upper mass concentrates program within the widest volume of the faceted form. The result is a spatial organization driven by the geometry of the envelope itself, each programmatic volume shaped by its relationship to the diagrid structure.

Key Considerations

- Interlocking programmatic volumes within a non-orthogonal faceted envelope
- Diagrid structural skin as both primary enclosure and spatial organizer
- Section-driven design: vertical voids and offset plates connect program layers
- Extended base dissolves threshold between site and interior
- Dense programmatic packing creates unexpected adjacencies and encounters
